(54) Title: **EFFICIENT IMAGE RECONSTRUCTION ALGORITHM FOR VARIABLE PITCH SPIRAL COMPUTED TOMOGRAPHY**

(57) Abstract: Reconstructing images of objects spirally scanned with two-dimensional detectors with a novel algorithm under a variable pitch(nonconstant speed), where the object is not restricted to moving at a constant velocity. The object can move at variable speeds (increasing, decreasing, combinations thereof) during the scan of the object. The image reconstruction process is proven to create an exact image of the object under the ideal circumstances. The algorithm can have a convolution-based FBP (Filtered Back Projection) structure and works very efficiently. The algorithm uses less computer power and combines the benefits of Exact Algorithms and Approximate algorithms. An object can be moved at a nonconstant speed through a rotating source and oppositely located detector. Additionally, at least one source and oppositely located detector can be mounted on a coil stand for generating the spiral scan.

WO 2004/084137 A2

EFFICIENT IMAGE RECONSTRUCTION ALGORITHM FOR VARIABLE PITCH SPIRAL COMPUTED TOMOGRAPHY

This invention is a Continuation-In-Part of United States Patent Application Serial No. 10/728,136, filed December 4, 2003 which claims the benefit of priority to U.S. Provisional Application, Serial No. 60/430,802, filed December 4, 2002, and is a Continuation-In-Part of United States Patent Application Serial No. 10/389,534 filed March 14, 2003 which is a Continuation-In-Part of Serial No. 10/389,090 filed March 14, 2003 which is a Continuation-In-Part of Serial No. 10/143,160 filed May 10, 2002 now U.S. Patent 6,574,299, which claims the benefit of priority to U.S. Provisional Application 60/312,827 filed August 16, 2001.

FIELD OF INVENTION

This invention relates to computer tomography, and in particular to processes and systems for reconstructing three dimensional images from the data obtained by a variable pitch spiral scan of an object, such as when the object moves at a variable speed, while the x-ray source rotates around the object.

BACKGROUND AND PRIOR ART

Over the last thirty years, computer tomography (CT) has gone from image reconstruction based on scanning in a slice-by-slice process to spiral scanning. From the 1970s to 1980s the slice-by-slice scanning was used. In this mode the incremental motions of the patient on the table through the gantry and the gantry rotations were performed one after another. Since the patient was stationary during the gantry rotations, the trajectory of the x-ray source around the patient was circular. Pre-

selected slices through the patient have been reconstructed using the data obtained by such circular scans.

From the mid 1980s to present day, spiral type scanning has become the preferred process for data collection in CT. Under spiral scanning a table with the patient continuously moves at a constant speed through the gantry that is continuously rotating about the table. At first, spiral scanning has used one-dimensional detectors, which receive data in one dimension (a single row of detectors). Later, two-dimensional detectors, where multiple rows (two or more rows) of detectors sit next to one another, have been introduced. In CT there have been significant problems for image reconstruction especially for two-dimensional detectors. In what follows the data provided by the two-dimensional detectors will be referred to as cone-beam (CB) data or CB projections.

Fig. 1 shows a typical arrangement of a patient on a table that moves at a constant speed within a rotating gantry having an x-ray tube source and a detector array, where cone beam projection data sets are received by the x-ray detector, and an image reconstruction process takes place in a computer with a display for the reconstructed image.

For three-dimensional (also known as volumetric) image reconstruction from the data provided by a spiral scan with two-dimensional detectors, there are two known groups of algorithms: Exact algorithms and Approximate algorithms; that each have known problems. Under ideal circumstances, exact algorithms can provide a replication of an exact image. Thus, one should expect that exact algorithms would produce images of good quality even under non-ideal (that is, realistic) circumstances. However, exact algorithms can be known to take many hours to provide an image reconstruction, and can take up great amounts of computer power when being used. These algorithms can require keeping considerable amounts of cone beam projections

in memory. Additionally, some exact algorithms can require large detector arrays to be operable and can have limits on the size of the patient being scanned.

Approximate algorithms possess a filtered back projection (FBP) structure, so they can produce an image very efficiently and using less computing power than Exact

5 algorithms. However, even under the ideal circumstances they produce an approximate image that may be similar to but still different from the exact image. In particular, Approximate algorithms can create artifacts, which are false features in an image. Under certain circumstances these artifacts could be quite severe.

To date, there are no known algorithms that can combine the beneficial
10 attributes of Exact and Approximate algorithms into a single algorithm that is capable of replicating an exact image under the ideal circumstances, uses small amounts of computer power, and reconstructs the exact images in an efficient manner (i.e., using the FBP structure) in the case of variable pitch spiral scanning. Here and everywhere below by the phrase that the algorithm of the invention reconstructs an exact image we
15 will mean that in theory the algorithm is capable of reconstructing an exact image.

Since in real life any data contains noise and other imperfections, no algorithm is capable of reconstructing an exact image.

Image reconstruction has been proposed in many U.S. Patents. See for example, U.S. Patents: 5,663,995 and 5,706,325 and 5,784,481 and 6,014,419 to Hu;
20 5,881,123 and 5,926,521 and 6,130,930 and 6,233,303 to Tam; 5,960,055 to Samaresekera et al.; 5,995,580 to Schaller; 6,009,142 to Sauer; 6,072,851 to Sivers; 6,173,032 to Besson; 6,198,789 to Dafni; 6,215,841 and 6,266,388 to Hsieh.

However, none of the patents overcome all of the deficiencies to image reconstruction referenced above.

25

SUMMARY OF THE INVENTION

A primary objective of the invention is to provide an improved process and system for reconstructing images of objects that have been scanned in a spiral fashion with variable pitch(at a nonconstant speed) and with two-dimensional detectors.

5 A secondary objective of the invention is to provide an improved process and system for reconstructing images of objects spirally scanned with variable pitch(at a nonconstant speed) that is known to theoretically be able to reconstruct an exact image and not an approximate image.

10 A third objective of the invention is to provide an improved process and system for reconstructing images of objects spirally scanned with variable pitch(at a nonconstant speed) that creates an exact image in an efficient manner using a filtered back projection (FBP) structure.

15 A fourth objective of the invention is to provide an improved process and system for reconstructing images of objects spirally scanned with variable pitch(at a nonconstant speed) that creates an exact image with minimal computer power.

A fifth objective of the invention is to provide an improved process and system for reconstructing images of objects spirally scanned with variable pitch(at a nonconstant speed) that creates an exact image with an FBP structure.

20 A sixth objective of the invention is to provide an improved process and system for reconstructing images of objects spirally scanned with variable pitch(at a nonconstant speed) that is CB projection driven allowing for the algorithm to work simultaneously with the CB data acquisition.

25 A seventh objective of the invention is to provide an improved process and system for reconstructing images of objects spirally scanned with variable pitch(at a nonconstant speed) that does not require storing numerous CB projections in computer memory.

An eighth objective of the invention is to provide an improved process and system for reconstructing images of objects spirally scanned with variable pitch (at a nonconstant speed) that allows for almost real time imaging to occur where images are displayed as soon as a slice measurement is completed.

5 A preferred embodiment of the invention uses a six overall step process for reconstructing the image of an object under a spiral scan. In a first step a current CB projection is measured. Next, a family of lines is identified on a detector according to a novel algorithm. Next, a computation of derivatives between neighboring projections occurs and is followed by a convolution of the derivatives with a filter
10 along lines from the selected family of lines. Next, using the filtered data, the image is updated by performing back projection. Finally, the preceding steps are repeated for each CB projection until an entire object has been scanned. This embodiment works with keeping several (approximately 2-4) CB projections in memory at a time and uses one family of lines.

15 Unlike the prior art, the invention is not limited to moving an object at a constant speed through a spiral scan. The object can be moved at a nonconstant speed through the gantry.

 Other embodiments allow for the object to remain stationary within a spiral coil type stand having multiple x-ray sources and oppositely located detectors
20 arranged along the coil stand which are activated sequentially from different locations on the coil stand. Still furthermore, the entire coil stand with fixed plural x-ray sources and oppositely located detectors rotates all about the object.

 Still furthermore, the spiral coil stand can contain a single x-ray source and oppositely located detector which moves along a spiral track about the fixed object at
25 constant and nonconstant speeds. Still furthermore, the spiral stand can include coil links that are not evenly spaced from one another so that the single x-ray source and

opposite located detector pass along the length of the object at different speeds. Thus, closely located links allow the single source and detector to pass at a slower rate over an object than distantly spaced apart coil links.

Further objects and advantages of this invention will be apparent from the following detailed description of the presently preferred embodiments, which is illustrated schematically in the accompanying drawings.

BRIEF DESCRIPTION OF THE FIGURES

Fig. 1 shows a typical arrangement of a patient on a table that moves within a rotating gantry having an x-ray tube source and a detector array, where cone beam projection data sets are received by the x-ray detector, and an image reconstruction process takes place in a computer with a display for the reconstructed image.

Fig. 2 shows an overview of the basic process steps of the invention.

Fig. 3 shows mathematical notations of the spiral scan about the object being scanned.

Fig. 4 illustrates a PI segment of an individual image reconstruction point.

Fig. 5 illustrates a stereographic projection from the current source position on to the detector plane used in the algorithm for the invention.

Fig. 6 illustrates various lines and curves, such as boundaries, on the detector plane.

Fig. 7 illustrates a family of lines used in the algorithm of the invention.

Fig. 8 is a four substep flow chart for identifying the set of lines, which corresponds to step 20 of Fig. 2.

Fig. 9 is a seven substep flow chart for preparation for filtering, which corresponds to step 30 of Fig. 2.

Fig. 10 is a seven substep flow chart for filtering, which corresponds to step 40 of Fig. 2.

Fig. 11 is an eight substep flow chart for backprojection, which corresponds to step 50 of Fig. 2.

Fig. 12 shows an arrangement of scanning an object with a spiral coil x-ray source where the object being scanned remains stationary inside.

5

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Before explaining the disclosed embodiments of the present invention in detail it is to be understood that the invention is not limited in its application to the details of the particular arrangements shown since the invention is capable of other
10 embodiments. Also, the terminology used herein is for the purpose of description and not of limitation.

Fig. 1 shows a typical arrangement of a patient on a table that moves within a rotating gantry having an x-ray tube source and a detector array, where CB projections
15 are received by the x-ray detector, and an image reconstruction process takes place in a computer 4 with a display 6 for displaying the reconstructed image. For the subject invention, the detector array is a two-dimensional detector array. For example, the array can include two, three or more rows of plural detectors in each row. If three rows are used with each row having ten detectors, then one CB projection set would
20 be thirty individual x-ray detections.

Fig. 2 shows an overview of the basic process steps of the invention that occur during the image reconstruction process occurring in the computer 4 using a first embodiment.

The first embodiment works with keeping several (approximately 2-4) CB
25 projections in computer memory at a time and uses one family of lines.

In the first step 10, a current CB projection set is taken. The next step 20 identifies a set of lines on a virtual x-ray detector array according to the novel algorithm, which will be explained later in greater detail. In the given description of the algorithm it is assumed that the detector array is flat, so the selected line can be a
5 straight tilted line across the array.

The next step 30 is the preparation for the filtering step, which includes computations of the necessary derivative of the CB projection data for the selected lines.

The next step 40 is the convolution of the computed derivative (the processed
10 CB data) with a filter along lines from the selected family of lines. This step can also be described as shift-invariant filtering of the derivative of the CB projection data. In the next step 50, the image of the object being computed is updated by performing back projection.

The invention will now be described in more detail by first describing the main
15 inversion formula followed by the novel algorithm.

Unlike the prior art, the invention can be used with objects that move at variable speeds through a rotating gantry. The object can accelerate, decelerate or combinations thereof. A slower speed through the rotating gantry can provide enhanced images of particular portions of an object as desired.

20 Experimentation in which the speed of the moving table through a rotating gantry was ramped up approximately 25%(twenty five percent) over the course of three(3) gantry rotations was done. Numerical experiments proved the following algorithms worked and demonstrated good image quality and high computational efficiency. Ramping down the speed of the moving table would inherently produce
25 similar results.

The variable pitch (variable speed) spiral path C of the x-ray source is described by the following equations and depicted in Fig. 3, which shows mathematical notations of the spiral scan about the object being scanned:

$$y_1(s) = R \cos(s), \quad y_2(s) = R \sin(s), \quad y_3(s) = z(s), \quad (1)$$

5 Here

s is a real parameter;

$z(s)$ is a function describing the third coordinate of the x-ray source on the spiral; the pitch is variable if $z'(s)$ is not a constant;

R is distance from the x-ray source to the isocenter.

10 The object being scanned is located inside an imaginary cylinder U of radius r , $r < R$ (see Fig. 3). Let ψ be a smooth function with the properties

$$\psi(0) = 0; \quad 0 < \psi'(t) < 1, \quad t \in [0, 2\pi]. \quad (2)$$

Even though it is not necessary, we will assume in addition that

$$\psi'(0) = 0.5; \quad \psi^{(2k+1)}(0) = 0, \quad k \geq 1. \quad (3)$$

15 Here and in what follows we assume that s_0, s_1 , and s_2 are always related by

$$s_1 = \psi(s_2 - s_0) + s_0 \quad \text{if} \quad s_0 \leq s_2 < s_0 + 2\pi, \quad (4)$$

$$s_1 = \psi(s_0 - s_2) + s_2 \quad \text{if} \quad s_0 - 2\pi < s_2 < s_0. \quad (5)$$

Conditions (2) and (3) can be easily satisfied. One can take, for example, $\psi(t) = t/2$, and this leads to

$$20 \quad s_1 = (s_0 + s_2)/2, \quad s_0 - 2\pi < s_2 < s_0 + 2\pi. \quad (6)$$

Denote

$$u(s_0, s_2) = \frac{(y(s_1) - y(s_0)) \times (y(s_2) - y(s_0))}{|(y(s_1) - y(s_0)) \times (y(s_2) - y(s_0))|} \text{sgn}(s_2 - s_0) \quad \text{if} \quad 0 < |s_2 - s_0| < 2\pi, \quad (7)$$

$$u(s_0, s_2) = \frac{\dot{y}(s_0) \times \ddot{y}(s_0)}{|\dot{y}(s_0) \times \ddot{y}(s_0)|} \quad \text{if} \quad s_2 = s_0. \quad (8)$$

Here

$y(s_0), y(s_1), y(s_2)$ are three points on the spiral related according to (4), (5);

$u(s_0, s_2)$ is a unit vector perpendicular to the plane containing the points

$y(s_0), y(s_1), y(s_2)$;

5 $\dot{y}(s) := dy/ds$;

$\ddot{y}(s) := d^2y/ds^2$.

Any point strictly inside the spiral belongs to a PI segment. A PI segment is a segment of line endpoints of which are located on the spiral and separated by less than one turn (see Fig. 4). We will assume that such a PI segment is unique. This holds, for

10 example, if $z'(s) = \text{const}$ or if $z''(s) = \text{const}$ and $z'(s)$ does not change sign or if

$z'(s) + z'''(s)$ does not change sign. Let $s = s_b(x)$ and $s = s_t(x)$ denote values of the

parameter corresponding to the endpoints of the PI segment containing a

reconstruction point x . We will call $I_{PI}(x) := [s_b(x), s_t(x)]$ the PI parametric interval.

The part of the spiral corresponding to $I_{PI}(x)$ will be denoted $C_{PI}(x)$ (see Fig. 4

15 which illustrates a PI segment of an individual image reconstruction point).

Next we fix a reconstruction point x inside the spiral and $s_0 \in I_{PI}(x)$. Find

$s_2 \in I_{PI}(x)$ such that the plane through $y(s_0), y(s_2)$, and $y(s_1(s_0, s_2))$ contains x .

More precisely, we have to solve for s_2 the following equation

$$(x - y(s_0)) \cdot u(s_0, s_2) = 0, \quad s_2 \in I_{PI}(x). \quad (9)$$

20 Such s_2 exists, is unique, and depends smoothly on s_0 . Therefore, this construction

defines $s_2 := s_2(s_0, x)$ and, consequently, $u(s_0, x) := u(s_0, s_2(s_0, x))$. Equation (9) can

be solved by a variety of methods, all known under the name "root finders". The main reconstruction formula now is as follows:

$$f(x) = -\frac{1}{2\pi^2} \int_{I_H(x)} \frac{1}{|x - y(s)|} \int_0^{2\pi} \frac{\partial}{\partial q} D_f(y(q), \Theta(s, x, \gamma)) \bigg|_{q=x} \frac{d\gamma}{\sin \gamma} ds,$$

(10)

where

f is the function representing the distribution of the x-ray attenuation

5 coefficient inside the object being scanned,

$$e(s, x) = \beta(s, x) \times u(s, x),$$

\times is the cross-product of two vectors,

$$\Theta(s, x, \gamma) := \cos \gamma \beta(s, x) + \sin \gamma e(s, x),$$

D_f is the cone beam transform of f :

$$10 \quad D_f(y, \Theta) = \int_0^\infty f(y + \Theta t) dt,$$

(11)

$\beta(s, x) := \frac{x - y(s)}{|x - y(s)|}$ is the unit vector from the focal point $y(s)$ pointing towards

the reconstruction point x .

15 Now we describe an efficient (that is, of the FBP type) implementation of inversion formula (10). It is clear from (9) that $s_2(s, x)$ actually depends only on s and $\beta(s, x)$.

Therefore, we can write

$$u(s, \beta) := u(s, s_2(s, \beta)), e(s, \beta) := \beta \times u(s, \beta), \beta \in S^2,$$

$$\Psi(s, \beta) := \int_0^{2\pi} \frac{\partial}{\partial q} D_f(y(q), \cos \gamma \beta + \sin \gamma e(s, \beta)) \bigg|_{q=x} \frac{1}{\sin \gamma} d\gamma,$$

20 (12)

$$f(x) = -\frac{1}{2\pi^2} \int_{I_H(x)} \frac{1}{|x - y(s)|} \Psi(s, \beta(s, x)) ds.$$

(13)

Here S^2 is the unit sphere.

To better understand equations (12), (13), we illustrate various important features on the detector array. Suppose first that the x-ray source is fixed at $y(s)$ for some $s \in I_{PI}(x)$. Project stereographically the upper and lower turns of the spiral
 5 onto the detector plane as shown in Fig. 5 which illustrates a stereographic projection from the current source position on to the detector plane used in the algorithm for the invention.

Since the detector array rotates together with the source, the detector plane depends on s and is denoted $DP(s)$. It is assumed that $DP(s)$ is parallel to the axis
 10 of the spiral and is tangent to the cylinder $y_1^2 + y_2^2 = R^2$ (cf. equation (1)) at the point opposite to the source. Thus, the distance between $y(s)$ and the detector plane is $2R$. Introduce coordinates in the detector plane as follows. Let the d_1 -axis be perpendicular to the axis of the spiral, and the d_2 -axis - parallel to it. This gives the following parametric curves:

$$15 \quad d_1(q) = 2R \frac{\sin(q-s)}{1 - \cos(q-s)}, \quad d_2(q) = 2 \frac{z(q) - z(s)}{1 - \cos(q-s)},$$

$$\Delta \leq q - s \leq 2\pi - \Delta \quad \text{or} \quad \Delta - 2\pi \leq q - s \leq -\Delta,$$

$$(14)$$

where Δ is determined by the radius r of the imaginary cylinder U inside which the patient is located (see Fig. 3): $\Delta = 2 \cos^{-1}(r/R)$. The top and bottom curves are
 20 denoted Γ_{top} and Γ_{bot} , respectively (see Fig. 6 which illustrates various lines and curves, such as boundaries, on the detector plane). The common asymptote of Γ_{top} and Γ_{bot} is denoted L_0 . Let \hat{x} denote the projection of x . Since $s \in I_{PI}(x)$, \hat{x} is projected into the area between Γ_{top} and Γ_{bot} (see Fig. 6). Fix

$s_2 \in [s - 2\pi + \Delta, s + 2\pi - \Delta]$, $s_2 \neq s$, and let $\Pi(s_2)$ denote the plane through $y(s)$, $y(s_2)$, and $y(s_1(s, s_2))$. If $s_2 = s$, $\Pi(s_2)$ is determined by continuity and coincides with the plane through $y(s)$ and parallel to $\dot{y}(s)$, $\ddot{y}(s)$. The family of lines $L(s_2)$ obtained by intersecting $\Pi(s_2)$ with the detector plane is shown in Fig. 7.

- 5 The main assumption under which equation (10) holds is that the curves Γ_{top} and Γ_{bot} are convex. This happens, for example, if $z'(s) = \text{const}$ or if $z''(s) = \text{const}$ and $z'(s)$ does not change sign or if $z'(s) + z'''(s)$ does not change sign.

- By construction, given any $x \in U$ with $\beta(s, x)$ parallel to $\Pi(s_2)$ and such that \hat{x} appears to the left (right) of the point of where the line $L(s_2)$ intersects Γ_{top} (Γ_{bot})
- 10 for the first time if \hat{x} is above (below) L_0 , s_2 used here is precisely the same as s_2 found by solving (9). The condition that we have formulated regarding the location of \hat{x} relative to s_2 and L_0 guarantees that $s_2 \in I_{PI}(x)$. Since $e(s, \beta) \cdot \beta = 0$, $|e(s, \beta)| = 1$, we can write:

$$\beta = (\cos \theta, \sin \theta); e(s, \beta) = (-\sin \theta, \cos \theta); \beta, e(s, \beta) \in \Pi(s_2).$$

15 (15)

Therefore,

$$\Psi(s, \beta) = \int_0^{2\pi} \frac{\partial}{\partial q} D_f(y(q), (\cos(\theta + \gamma), \sin(\theta + \gamma))) \bigg|_{q=s} \frac{1}{\sin \gamma} d\gamma, \beta \in \Pi(s_2).$$

(16)

- Equation (16) is of convolution type and one application of Fast Fourier Transform
- 20 (FFT) gives values of $\Psi(s, \beta)$ for all $\beta \in \Pi(s_2)$ at once.

Equations (13) and (16) would represent that the resulting algorithm is of the FBP type. This means that processing of every CB projection consists of two steps. First, shift-invariant and x -independent filtering along a family of lines on the detector is

- performed. Second, the result is back-projected to update the image matrix. The main property of the back-projection step is that for any point \hat{x} on the detector the value obtained by filtering at \hat{x} is used for all points x on the line segment connecting the current source position $y(s)$ with \hat{x} . Since $\partial/\partial q$ in (16) is a local operation, each
- 5 CB projection is stored in memory as soon as it has been acquired for a short period of time for computing this derivative at a few nearby points and is never used later.

Now we describe the algorithm in detail following the six steps 10-60 shown in Fig. 2.

Step 10. Load the current CB(cone beam) projection into computer memory.

- 10 Suppose that the mid point of the CB projections currently stored in memory is $y(s_0)$.

The detector plane corresponding to the x-ray source located at $y(s_0)$ is denoted

$DP(s_0)$.

Step 20. Fig. 8 is a four substep flow chart for identifying the set of lines, which

corresponds to step 20 of Fig. 2. Referring to Fig. 8, the set of lines can be selected by

- 15 the following substeps 21, 22, 23 and 24.

Step 21. Choose a discrete set of values of the parameter s_2 inside the interval

$$[s_0 - 2\pi + \Delta, s_0 + 2\pi - \Delta].$$

Step 22. For each selected s_2 compute the vector $u(s_0, s_2)$ according to

equations (7), (8).

- 20 Step 23. For each $u(s_0, s_2)$ computed in Step 22 find a line which is obtained by

intersecting the plane through $y(s_0)$ and perpendicular to the said vector

$u(s_0, s_2)$ with the detector plane $DP(s_0)$.

Step 24. The collection of lines constructed in Step 23 is the required set of lines (see Fig. 7 which illustrates a family of lines used in the algorithm of the invention).

5 **Step 30.** Preparation for filtering

Fig. 9 is a seven substep flow chart for preparation for filtering, which corresponds to step 30 of Fig. 2, which will now be described.

Step 31. Fix a line $L(s_2)$ from the said set of lines obtained in Step 20.

10 Step 32. Parameterize points on the said line by polar angle γ in the plane through $y(s_0)$ and $L(s_2)$.

Step 33. Choose a discrete set of equidistant values γ_j that will be used later for discrete filtering in Step 40.

Step 34. For each γ_j find the unit vector β_j which points from $y(s_0)$ towards the point on $L(s_2)$ that corresponds to γ_j .

15 Step 35. Using the CB projection data $D_f(y(q), \Theta)$ for a few values of q close to s_0 find numerically the derivative $(\partial/\partial q)D_f(y(q), \Theta)|_{q=s_0}$ for all $\Theta = \beta_j$.

Step 36. Store the computed values of the derivative in computer memory.

20 Step 37. Repeat Steps 31-36 for all lines $L(s_2)$ identified in Step 20. This way we will create the processed CB data $\Psi(s_0, \beta_j)$ corresponding to the x-ray source located at $y(s_0)$.

Step 40. Filtering

Fig. 10 is a seven substep flow chart for filtering, which corresponds to step 40 of Fig. 2, which will now be described.

Step 41. Fix a line from the said family of lines identified in Step 20.

5 Step 42. Compute FFT of the values of the said processed CB data computed in Step 30 along the said line.

Step 43. Compute FFT of the filter $1/\sin \gamma$

Step 44. Multiply FFT of the filter $1/\sin \gamma$ (the result of Steps 43) and FFT of the values of the said processed CB data (the result of Steps 42).

Step 45. Take the inverse FFT of the result of Step 44.

10 Step 46. Store the result of Step 45 in computer memory.

Step 47. Repeat Steps 41-46 for all lines in the said family of lines. This will give the filtered CB data $\Phi(s_0, \beta_j)$.

By itself the filtering step is well known in the field and can be implemented, for example, as shown and described in U.S. Patent 5,881,123 to Tam, which
15 is incorporated by reference.

Step 50. Back-projection

Fig. 11 is an eight substep flow chart for backprojection, which corresponds to step 50 of Fig. 2, which will now be described.

20 Step 51. Fix a reconstruction point x , which represents a point inside the patient where it is required to reconstruct the image.

Step 52. If s_0 belongs to $I_{p_j}(x)$, then the said filtered CB data affects the image at x and one performs Steps 53-58. If s_0 is not inside the interval

$I_{pj}(x)$, then the said filtered CB data is not used for image reconstruction at x . In this case go back to Step 51 and choose another reconstruction point.

Step 53. Find the projection \hat{x} of x onto the detector plane $DP(s_0)$ and the unit vector $\beta(s_0, x)$, which points from $y(s_0)$ towards x .

5 Step 54. Using equation (9) identify the lines from the said family of lines and points on the said lines that are close to the said projection \hat{x} . This will give a few values of $\Phi(s_0, \beta_j)$ for β_j close to $\beta(s_0, x)$.

Step 55. With interpolation estimate the value of $\Phi(s_0, \beta(s_0, x))$ from the said values of $\Phi(s_0, \beta_j)$ for β_j close to $\beta(s_0, x)$.

10 Step 56. Compute the contribution from the said filtered CB data to the image being reconstructed at the point x by dividing $\Phi(s_0, \beta(s_0, x))$ by $-2\pi^2 |x - y(s_0)|$.

Step 57. Add the said contribution to the image being reconstructed at the point x according to a pre-selected scheme (for example, the Trapezoidal
15 scheme) for approximate evaluation of the integral in equation (15).

Step 58. Go to Step 51 and choose a different reconstruction point x .

Step 60. Go to Step 10 (Fig. 2) and load the next CB projection into computer memory. The image can be displayed at all reconstruction points x for which the
20 image reconstruction process has been completed (that is, all the subsequent CB projections are not needed for reconstructing the image at those points). Discard from the computer memory all the CB projections that are not needed for image reconstruction at points where the image reconstruction process has not completed.

The algorithm concludes when the scan is finished or the image reconstruction process has completed at all the required points.

The invention can work with other types of variable pitch(nonconstant speed) spiral scans. Fig. 12 shows an arrangement 500 of scanning an object 515 such as a human body, on a stationary table 510 within a spiral coil stand the object 515 being scanned remains stationary inside. The coil stand can be located inside of a chamber, or be a virtual coil stand within a chamber. As previously described, unlike the prior art, the invention is not limited to moving an object at a constant speed through a spiral scan. The object 515 can remain stationary within a stationary spiral coil type stand, where multiple x-ray sources S1, S2, S3, S4, S5, S6 and oppositely located detectors D1, D2, D3, D4, D5, D6 arranged along the stationary coil stand 600 emit x-rays in a sequential manner about the stationary object 515 such as from right to left, left to right, the middle to the left, the middle to the right, and combinations thereof, to generate a spiral scan

Still furthermore, the coil stand 600 can have fixed multiple x-ray sources and detectors so that the entire coil stand 600 can rotate about the object 515, and generate a spiral scan.

Still furthermore, the spiral coil stand 600 can contain a single x-ray source S1 and oppositely located detector D1 which moves along a spiral track on the stand 600 about the fixed object 510 at constant and nonconstant speeds. Still furthermore, the spiral stand 600 can include coils links 610, 620, 630, 640, 650, 660, 670 that are not evenly spaced from one another so that the single x-ray source S1 and opposite located detector D1 moving at a constant speed ends up passing along the length of the object 515 at different speeds. Thus, closely located links 610, 620 allow the

single source S1 and detector D1 to pass at a slower rate over an object than distantly spaced apart coil links 650, 660, 670.

The spiral coil stand embodiments described above can also work with constant pitch(constant speed) applications.

5

Other Embodiments of the invention are possible. For example, one can integrate by parts in equation (10) as described in the inventor's previous U.S. Patent Application

Serial No. 10/143,160 filed May 10, 2002 now U.S. Patent 6,574,299, now
10 incorporated by reference, to get an exact FBP-type inversion formula which requires keeping only one CB projection in computer memory. The algorithmic implementation of this alternative embodiment can be similar to and include the algorithmic implementation of Embodiment Two in the inventor's previous U.S. Patent Application

15 Serial No. 10/143,160 filed May 10, 2002 now U.S. Patent 6,574,299, now incorporated by reference.

Although the preferred embodiments describe applications of using x-ray sources for creating data for image reconstruction, the invention can be applicable with other sources such as but not limited to early arriving photons that create line
20 integral data for image reconstruction.

While the invention has been described, disclosed, illustrated and shown in various terms of certain embodiments or modifications which it has presumed in practice, the scope of the invention is not intended to be, nor should it be deemed to be, limited thereby and such other modifications or embodiments as may be suggested by the
25 teachings herein are particularly reserved especially as they fall within the breadth and scope of the claims here appended.

I claim:

1. A method of reconstructing images from data provided by at least one detector, comprising the steps of:
 - 5 variable pitch spiral scanning an object with at least one detector with at least one cone beam projection source; and
reconstructing an exact image of the scanned object in an efficient manner with a convolution based FBP (Filtered Back Projection) algorithm.
- 10 2. The method of claim 1, wherein the scanning step further includes the step of:
moving a table supporting the object through a rotational scanner with non-constant speed.
3. The method of claim 1, wherein the step of reconstructing further includes the
15 step of:
shift invariant filtering of the cone beam projections; and
back projection updating the image of the scanned object.
4. The method of claim 1, wherein the step of reconstructing includes the steps
20 of:
storing approximately 2 to approximately 4 cone beam (CB) projections in memory at a time; and
using one family of lines for the step of reconstructing.
- 25 5. The method of claim 1, wherein the step of reconstructing includes the steps of:

storing 1 cone beam (CB) projection in memory at a time; and
using one family of lines for the step of reconstructing.

6. The method of claim 1, wherein the scanning step further includes the step of:
5 supporting the object in a stationary position within a coil stand; and
moving the one source and the one detector along the coil stand about the
object at a constant speed to generate a spiral scan.

7. The method of claim 1, wherein the scanning step further includes the step of:
10 supporting the object in a stationary position within a coil stand; and
moving the one source and the one detector along the coil stand about the
object at a nonconstant speed to generate a spiral scan.

8. The method of claim 1, wherein the scanning step further includes the step of:
15 supporting the object in a stationary position within a coil stand; and
placing plural sources and oppositely located detectors on the coil stand about
the object; and
sequentially activating the cone beam projections to generate a spiral scan.

20 9. The method of claim 1, wherein the scanning step further includes the step of:
supporting the object in a stationary position within a coil stand; and
placing plural sources and oppositely located detectors on the coil stand about
the object; and
rotating the coil stand about the object to generate a spiral scan.

25

10. A method of computing images derived from a variable pitch spiral computer tomography with detectors, comprising the steps of:

(a) collecting cone beam data from a detector during a variable pitch spiral scan of an object;

5 (b) identifying lines on a plane Π intersecting the cone beam, wherein the step (b) of identifying lines includes the steps of:

(bi) choose a discrete set of values of the parameter s_2 inside an interval containing s_0 , where s_0 and s_2 are values of the parameter along the spiral;

(bii) compute the vector $u(s_0, s_2)$ for each selected s_2 according to equations

$$10 \quad u(s_0, s_2) = \frac{(\gamma(s_1) - \gamma(s_0)) \times (\gamma(s_2) - \gamma(s_0))}{|(\gamma(s_1) - \gamma(s_0)) \times (\gamma(s_2) - \gamma(s_0))|} \text{sgn}(s_2 - s_0) \text{ if } 0 < |s_2 - s_0| < 2\pi,$$

$$u(s_0, s_2) = \frac{\dot{\gamma}(s_0) \times \ddot{\gamma}(s_0)}{|\dot{\gamma}(s_0) \times \ddot{\gamma}(s_0)|} \text{ if } s_2 = s_0.$$

where, $\gamma(s_0), \gamma(s_1), \gamma(s_2)$ are three points on the spiral related according to the

15 following equations

$$s_1 = \psi(s_2 - s_0) + s_0 \quad \text{if } s_0 \leq s_2 < s_0 + 2\pi,$$

$$s_1 = \psi(s_0 - s_2) + s_2 \quad \text{if } s_0 - 2\pi < s_2 < s_0,$$

and ψ is a function with the properties

$$\psi(0) = 0; \quad 0 < \psi'(t) < 1, \quad t \in [0, 2\pi];$$

20 $u(s_0, s_2)$ is a unit vector perpendicular to the plane containing the

points $\gamma(s_0), \gamma(s_1), \gamma(s_2)$;

$$\dot{\gamma}(s) := d\gamma/ds;$$

$$\ddot{y}(s) := d^2 y / ds^2;$$

- (biii) find a line for each $u(s_0, s_2)$ which is obtained by intersecting the plane through $y(s_0)$ and perpendicular to the said vector $u(s_0, s_2)$ with the plane Π ; and
- (biv) repeating steps (bi-biii), and forming a family of lines from a collection
- 5 of the lines ;
- (c) preprocessing and shift invariant filtering said data along said lines ;
- (d) back projecting said filtered data to form a precursor of said image; and
- (e) repeating steps a, b, c, and d until an image of the object is completed.
- 10 11. The method of claim 10, wherein the scan includes an x-ray exposure of the object.
12. The method of claim 10, further including the step of
- (b5) preparing the data prior to the step (c) filtering step of:
- 15 (b5i) fixing a line $L(s_2)$ from the set of lines obtained in step (b);
- (b5ii) parameterizing points on the lines by polar angle γ in the plane through $y(s_0)$ and $L(s_2)$;
- (b5iii) choosing a discrete set of equidistant values γ_j ;
- (b5iv) find the unit vector β_j for each γ_j which points from $y(s_0)$ towards
- 20 the point on $L(s_2)$ that corresponds to γ_j ;
- (b5v) computer derivatives using the CB projection data $D_f(y(q), \Theta)$ for a few values of q close to s_0 using equation $(\partial/\partial q)D_f(y(q), \Theta)|_{q=s_0}$ for all $\Theta = \beta_j$;

(b5vi) store the computed derivatives; and

(b5vii) repeat steps (b5i) to b5vi for all lines $L(s_2)$ identified step (b), in order to create processed CB data $\Psi(s_0, \beta_j)$ corresponding to the x-ray source located at $y(s_0)$.

5

13. The method of claim 10, wherein the back-projection step (d) includes the steps of:

(di) fix a reconstruction point x , which represents a point inside the object being scanned where it is required to reconstruct the image;

10 (dii) if s_0 belongs to $I_{PI}(x)$, then the said filtered CB data affects the image at x and one performs Steps (diii) to (dviii), if s_0 is not inside interval $I_{PI}(x)$, then the said filtered CB data is not used for image reconstruction at x and go back to step (di) and choose another reconstruction point. Here $I_{PI}(x)$ the PI parametric interval;

15 (diii) find the projection \hat{x} of x onto a detector plane $DP(s_0)$ and unit vector $\beta(s_0, x)$, which points from $y(s_0)$ towards x ;

(div) identify lines from family of lines and points on the said lines that are close to the said projection \hat{x} , using equation

$$(x - y(s_0)) \cdot u(s_0, s_2) = 0, \quad s_2 \in I_{PI}(x);$$

20 (dv) using interpolate find value of $\Phi(s_0, \beta(s_0, x))$ from $\Phi(s_0, \beta_j)$ for β_j close to $\beta(s_0, x)$;

(dvi) compute contribution from filtered CB data to the image being

reconstructed at the point x by dividing $\Phi(s_0, \beta(s_0, x))$ by $-2\pi^2 |x - y(s_0)|$;

(dvii) add the contribution to the image being reconstructed at the point x according to a pre-selected scheme; and
(dviii) go to step (di) and choose a different reconstruction point x .

5 14. The method of claim 10, further comprising the steps of:
storing approximately 2 to approximately 4 cone beam (CB) projections in
memory at a time; and
using one family of lines for the step of reconstructing.

10 15. The method of claim 10, further comprising the steps of:
storing 1 cone beam(CB) projection in memory at a time; and
using one family of lines for reconstructing the exact image.

16. The method of claim 10, further comprising the step of:
15 moving the object at a nonconstant speed through a rotating source and
oppositely located detector to generate the variable pitch spiral scan .

17. The method of claim 10, further comprising the step of:
positioning the object in a stationary position within a coil stand; and
20 generating the spiral scan from at least one source and at least one oppositely
located detector located on the coil stand.

18. A method of identifying lines on a plane Π used for reconstructing images
based on a variable pitch spiral scan of an object in a computer tomography system,
25 comprising the steps of:

(i) choose a discrete set of values of the parameter s_2 inside an interval containing s_0 , where s_0 and s_2 are values of the parameter along the spiral scan path ;

(ii) compute the vector $u(s_0, s_2)$ for each selected s_2 according to equations

$$5 \quad u(s_0, s_2) = \frac{(y(s_1) - y(s_0)) \times (y(s_2) - y(s_0))}{|(y(s_1) - y(s_0)) \times (y(s_2) - y(s_0))|} \text{sgn}(s_2 - s_0) \text{ if } 0 < |s_2 - s_0| < 2\pi,$$

$$u(s_0, s_2) = \frac{\dot{y}(s_0) \times \ddot{y}(s_0)}{|\dot{y}(s_0) \times \ddot{y}(s_0)|} \text{ if } s_2 = s_0.$$

where, $y(s_0), y(s_1), y(s_2)$ are three points on the spiral related according to the

10 following equations

$$s_1 = \psi(s_2 - s_0) + s_0 \text{ if } s_0 \leq s_2 < s_0 + 2\pi,$$

$$s_1 = \psi(s_0 - s_2) + s_2 \text{ if } s_0 - 2\pi < s_2 < s_0,$$

and ψ is a function with the properties

$$\psi(0) = 0; \quad 0 < \psi'(t) < 1, \quad t \in [0, 2\pi]; u(s_0, s_2) \text{ is a unit vector}$$

15 perpendicular to the plane containing the points $y(s_0), y(s_1), y(s_2)$;

$$\dot{y}(s) := dy/ds;$$

$$\ddot{y}(s) := d^2y/ds^2;$$

(iii) find a line for each $u(s_0, s_2)$ which is obtained by intersecting the plane through $y(s_0)$ and perpendicular to the said vector $u(s_0, s_2)$ with the plane Π ; and

20 (iv) repeating steps (i-iii), and forming a family of lines from a collection of the lines so that an image is reconstructed using the lines.

19. The method of claim 18, further comprising the step of:
moving the object at a nonconstant speed through a rotating source and
oppositely located detector to generate the variable pitch spiral scan .
- 5 20. The method of claim 18, further comprising the step of:
positioning the object in a stationary position within a coil stand; and
generating the spiral scan from at least one source and at least one oppositely
located detector located on the coil stand.

Step 20. Finding families of lines for filtering

Fig. 9

**Step 30. Preparation for
filtering**

Step 31. Fix a line $L(s_2)$ from the said set of lines obtained in Step 20.

Step 32. Parameterize points on the said line by polar angle γ in the plane through $y(s_0)$ and $L(s_2)$.

Step 33. Choose a discrete set of equidistant values γ_j that will be used later for discrete filtering in Step 40.

Step 34. For each γ_j find the unit vector β_j which points from $y(s_0)$ towards the point on $L(s_2)$ that corresponds to γ_j .

Step 35. Using the CB projection data $D_r(y(q), \Theta)$ for a few values of q close to s_0 find numerically the derivative $(\partial/\partial q)D_r(y(q), \Theta)|_{q=s_0}$ for all $\Theta = \beta_j$.

Step 36. Store the computed values of the derivative in computer memory.

Step 37. Repeat Steps 31-36 for all lines $L(s_2)$ identified in Step 20. This way we will create the processed CB data $\Psi(s_0, \beta_j)$
